Primary Liver Tumors

Primary cancer in healthy liver
Size, number and location: where is the limit for surgical resection?

Catherine HUBERT, MD, PhD.

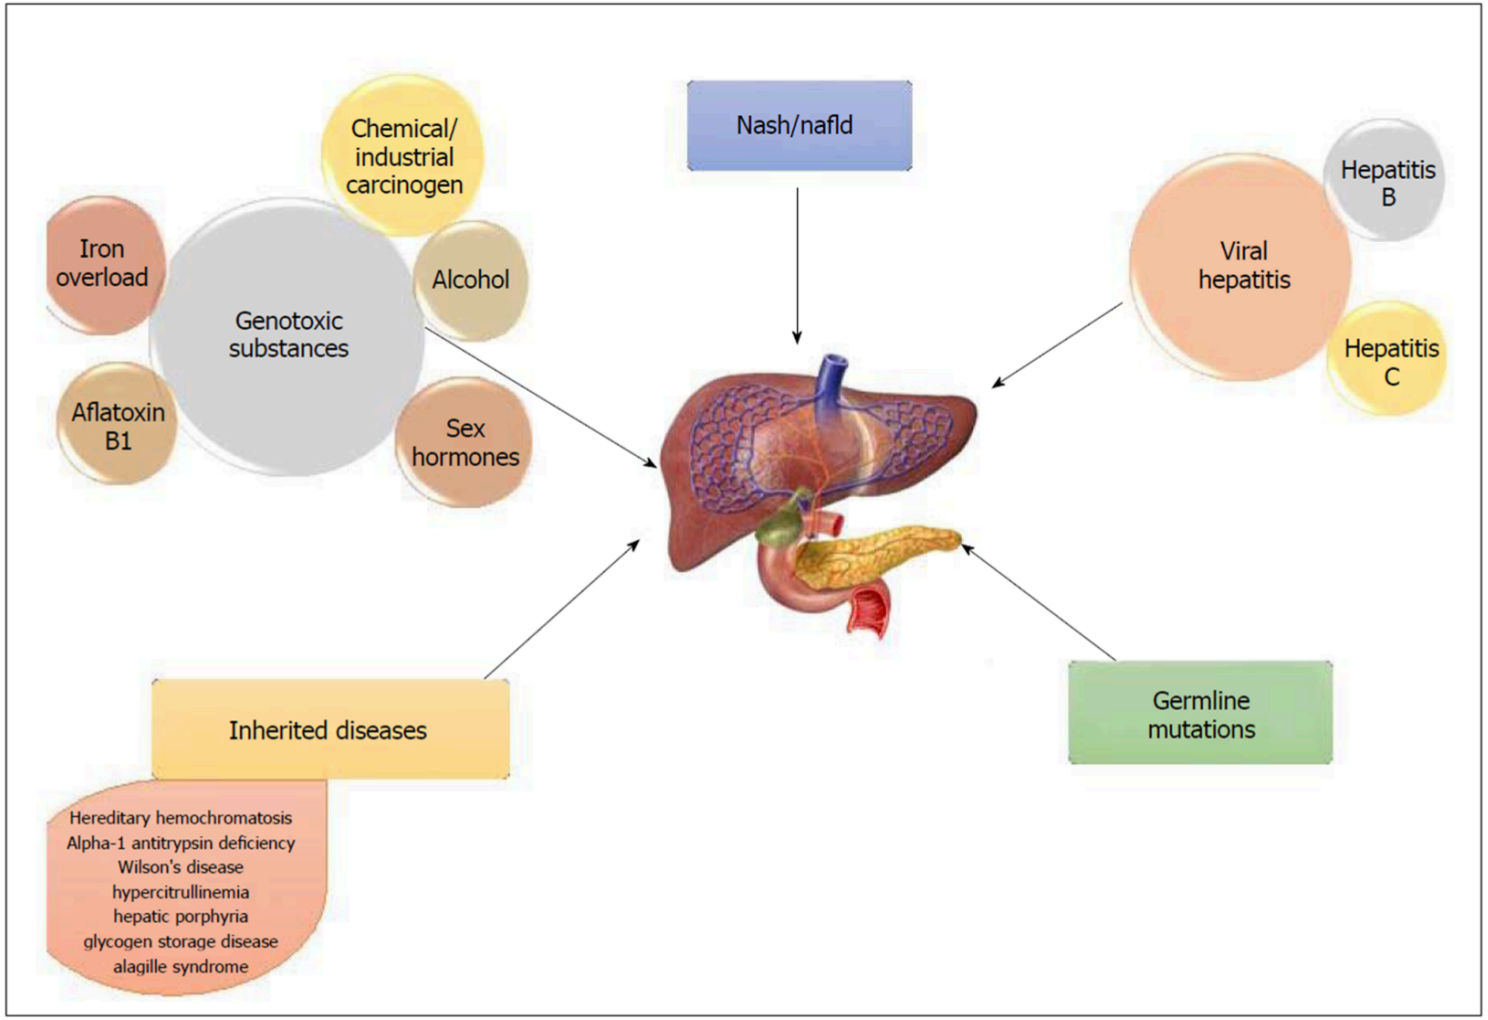
Mechelen

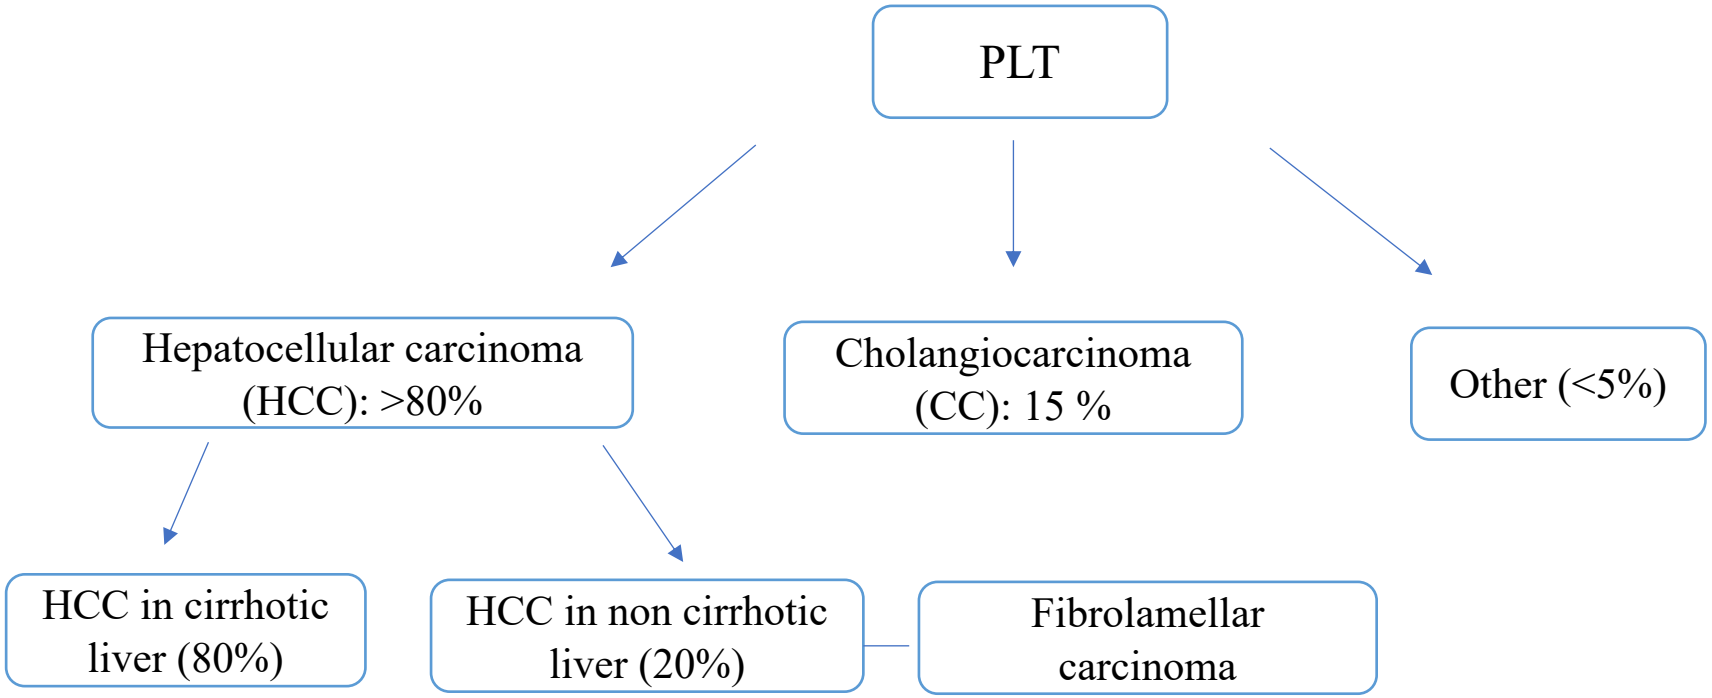
Non cirrhotic liver ≠ healthy liver



PLC can develop directly from inflammation without cirrhosis

Primary Liver Tumour (PLT)

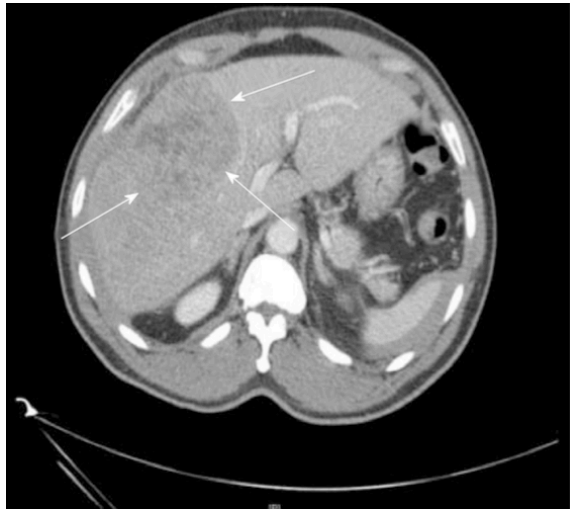
- 6th most common malignant tumor and 3rd leading cause of cancer-related death worldwide



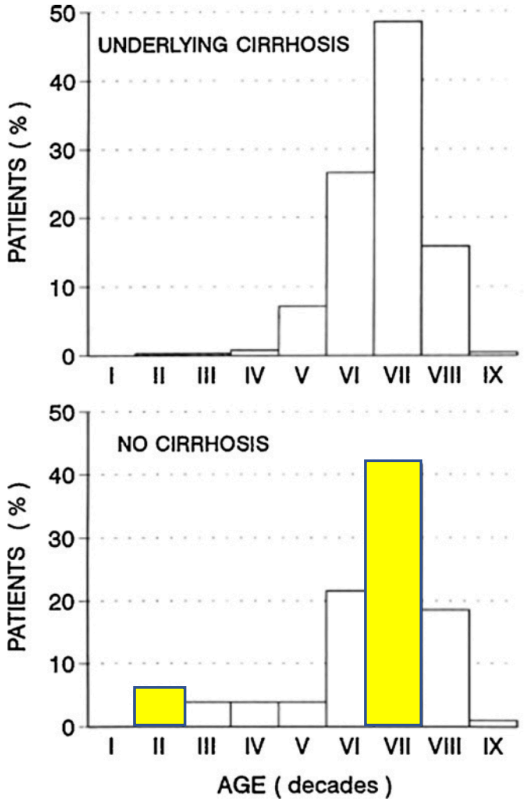
Calvet et al. J. of hepatology 1990
Gaddikeri et al. Am J Roentgenology 2014
Lee et al. Eur. J of radiology 2017

1. Non cirrhotic conventional HCC

1. Non cirrhotic conventional HCC



- 5.5 per 100000 in male and 2 per 100000 in female (USA)
- More frequent in developed countries
- Bimodal age distribution (2nd and 7th decade of life).
- Often detected at advanced stage
- Lack of significant data on HCC that arises in non-cirrhotic liver
- α-FP is normal in 60%
- Portal vein invasion +++



Trevisani et al. Digestive and liver disease 2010
Yan Liu et al. Med Sci Monit 2019

Treatment of choice = radical liver resection

- Contraindication: extrahepatic spread of the disease or anatomical constraints related to the tumor.
- Majority of the patients requires a major hepatic resection
- Feasible due to the preserved liver function and low perioperative mortality compared to cirrhotic livers.

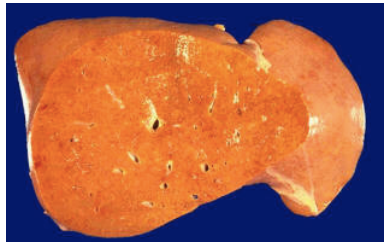
Trevisani et al. Digestive and liver disease 2010
Chiche et al. J.Visceral Surg. 2010
Yan Liu et al. Med Sci Monit 2019

Treatment of choice = radical liver resection

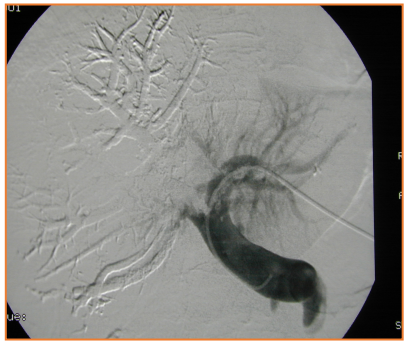
Need for an accurate assessment of :

- The tumour characteristics (vascular relationship/ tumour thrombus in the PV, satellites nodules,…)
- Extra-hepatic extension
- The quality of the liver parenchyma and the volume of the future liver remnant
- *→Good quality CT scan of the chest and abdomen*

25-30 %



30 - 35 %



PVE

Trevisani et al. Digestive and liver disease 2010
Chiche et al. J.Visceral Surg. 2010
Yan Liu et al. Med Sci Monit 2019

Treatment of choice = radical liver resection

Surgical management recommandations :

- Predilection of HCC for endoportal spread→ anatomical resection
- 1 centimeter margin
- Additional lymphadectomy in young patients (FLC!)
- Recurrences must be aggressively treated (2nd R0 resection)

Boudjema et al. Monographie de l'AFC 2006
Chiche et al. J.Visceral Surg. 2010
Laurent et al. J am coll surg 2006

Prognostic factors of HCC in non-cirrhotic liver

Table 1 prognostic factors for hepatocellular cancer in non-cirrhotic liver.

1er author (references)	Number of patients	Dates of study	Overall 5 Year survival (%)	Factors of poor prognosis
Bege et al. [15]	116	1987–2005	40.0	R1 resection Vascular involvement HBV infection
Dupont-Bierre et al. [16]	84	1998–2003	44.4	Multiple tumors Gross vascular involvement
Lang et al. [17]	83	1998–2005	30.0	UICC stage Vascular involvement Tumor grade
Laurent et al. [18]	108	1987–2005	29.0	Blood transfusion Absence of capsule Satellite nodules Resection margin < 1cm

No	–	–	–
Yes	1.07	2.93 (2.28–3.76)	**<0.001**

Table 4 Risk score

	Points
Sex	
Female	0
Male	1
Tumour Size	
<35 mm	0
35–94 mm	1
95 + mm	2
Number of Tumours	
Solitary	0
Multiple	1
Tumour Lobes	
Unilobar	0
Bilobar	1
Major Vascular Invasion	
No	0
Yes	4

The score is based on the multivariable model in Table 3. The number of points associated with each factor was calculated by multiplying the coefficient by four, and rounding to the nearest integer. The score can be calculated for an individual by looking up the points value of each factor, and adding together the resulting four numbers to give a score in the range 0–9.

Table 7 Risk score validation

Score	Risk Category	*N*	5 Year Survival	HR (95% CI)
SEER Derivation Set				
0–1	Low	621	68.0%	–
2–4	Moderate	1462	52.2%	1.72 (1.43–2.08)
5+	High	200	24.5%	4.16 (3.26–5.30)

3. Intrahepatic cholangiocarcinoma (ICC)

3. Intrahepatic cholangiocarcinoma (ICC)

- Rare (0.85 per 100 000 population in 2000 in USA)
- The only potentially curative treatment option for patients who have resectable disease is surgery.
- But …with a 5-year survival rate of only 20% to 35% (tumor recurrence).
- Lack of reports on the characteristics of patients with ICC as well as predictors of recurrence and survival

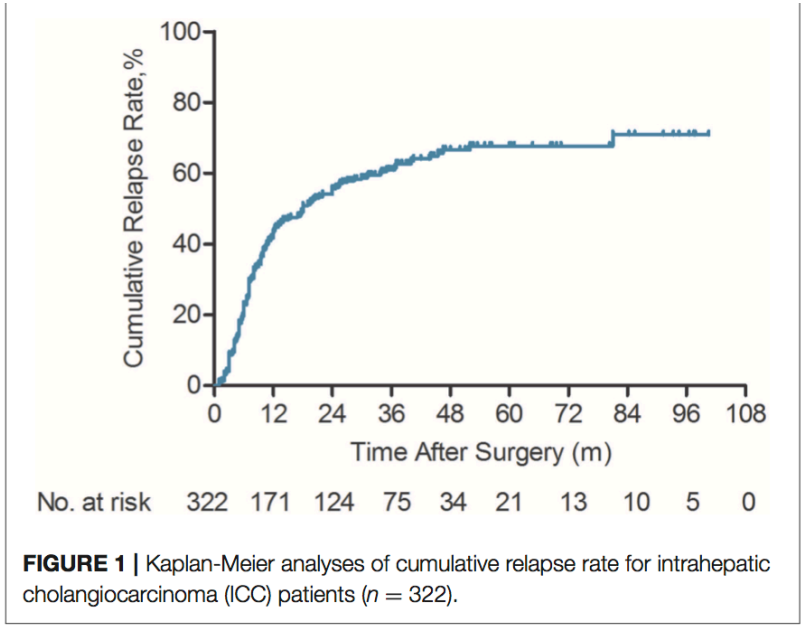

FIGURE 1 | Kaplan-Meier analyses of cumulative relapse rate for intrahepatic cholangiocarcinoma (ICC) patients ($n = 322$).

The overall survival of the early relapse group was lower than that of the late relapse group ($P < 0.0001$)

Treatment and Prognosis for Patients With Intrahepatic Cholangiocarcinoma
Systematic Review and Meta-analysis

Michael N. Mavros, MD; Konstantinos P. Economopoulos, MD;
Vangelis G. Alexiou, MD, PhD; Timothy M. Pawlik, MD, MPH, PhD

57 Studies included; 4756 patients

Patients characteristics:

- Median age range from 47to 69
- 57% of male patients
- Tumor median size: 4,5 -8 cm
- LN M+: 34%
- Major LR: 82%
- Lymphadenectomy: 67%

Survival:

- Median OS=28 months (9-53)
- 5 years OS=30% (5%-56%)

Prognostic factors of shorter OS (multivariate analysis):

- Age
- Tumor size
- Multiple tumors
- Lymphnodes metastases
- Vascular invasion

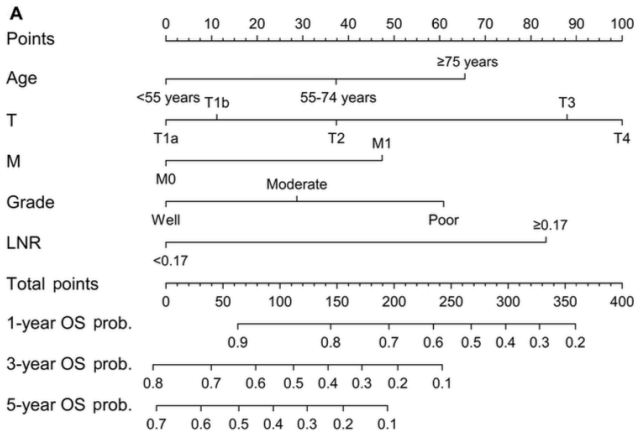
ORIGINAL RESEARCH

Nomograms for predicting overall survival and cancer-specific survival in patients with surgically resected intrahepatic cholangiocarcinoma



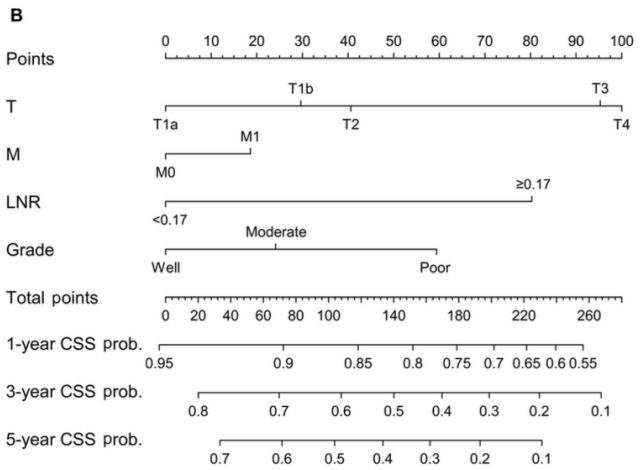


Figure 2 Nomograms predicting 1-, 3- and 5-year OS (**A**) and CSS (**B**) in patients with ICC after surgery. Each subtype within these variables was assigned a score on the point scale. By summing up the total score and locating it on the total point scale, we could draw a vertical line down to get the nomogram-predicted probability at each time point.
Abbreviations: CSS, cancer-specific survival; ICC, intrahepatic cholangiocarcinoma; LNR, lymph node ratio; OS, overall survival.

Kexin Ma et al. 2019

947 patients

In Cox regression multivariate analysis:

- Age, T stage, M stage, lymphnode ratio (LNR) level and tumor grade were independent prognostic predictors for OS in ICC patients.

- T stage, M stage, lymphnode ratio (LNR) level and tumor grade were independent prognostic predictors for DFS in ICC patients.

AIM :to characterize the impact of ICC tumor burden on patient prognosis relative to other clinicopathological factors

In press

Statistics

The primary outcome for the survival analysis was **overall survival** (by Kaplan-Meier methodology)

Cox proportional hazards regression analysis was used to evaluate any **association among variables and survival outcomes.** Variables with a P value <0.1 on univariable analysis were included in the final multivariable model.

The **concordance index** (c-index) was used to assess the predictive abilities of different methods **to estimate tumor burden.** C-index is a statistic comparable to the AUC varying from 50% (no discrimination) to 100% (perfect discrimination).

The Classification and Regression Tree (**CART**) model, a machine-learning used **to identify groups of patients with a homogeneous risk of death and investigate the hierarchical association between variables and OS.**

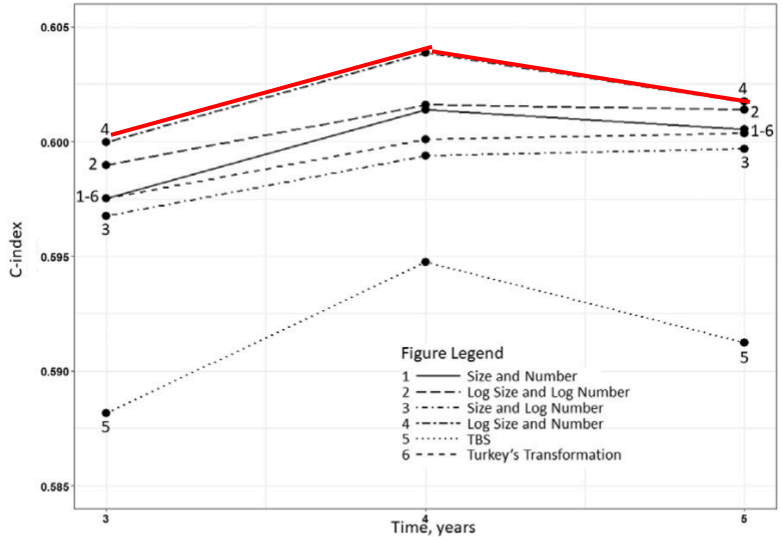

Fig 1. Trends of c-index values calculated for the different approaches to estimating ICC tumor burden.

Table III
Multivariable Cox proportional hazards regression analysis of risk factors associated with OS for patients undergoing liver resection for ICC

Variables	HR	95% CI	*P* Value
Tumor morphology type			
MF/IG	Reference	—	—
PI/MF+PI	1.41	1.09–1.83	.008
Margins			
Negative	Reference	—	—
Positive	1.43	1.10–1.87	.008
Tumor size (logistic transformation) (cm)	1.58	1.32–1.89	<.001
Number of tumors	1.19	1.12–1.27	<.001
Tumor grade			
Well to moderate	Reference	—	—
Poor to undifferentiated	1.49	1.19–1.88	<.001
Lymph node status			
Negative	Reference	—	—
Positive	2.45	1.89–3.23	<.001
Not assessed	1.56	1.24–1.97	<.001

In the multivariable Cox regression model, the risk of death increased by:
-58% for each increase in log tumor size (P < 0.001)
- 19% for each additional ICC lesion (P < 0.001).

Log tumor size and ICC lesion numbers have been identified as the best estimators of tumor burden

CART Algorythm

Lymph node status was the strongest predictor of survival in both the "classical" survival analysis and in the CART model

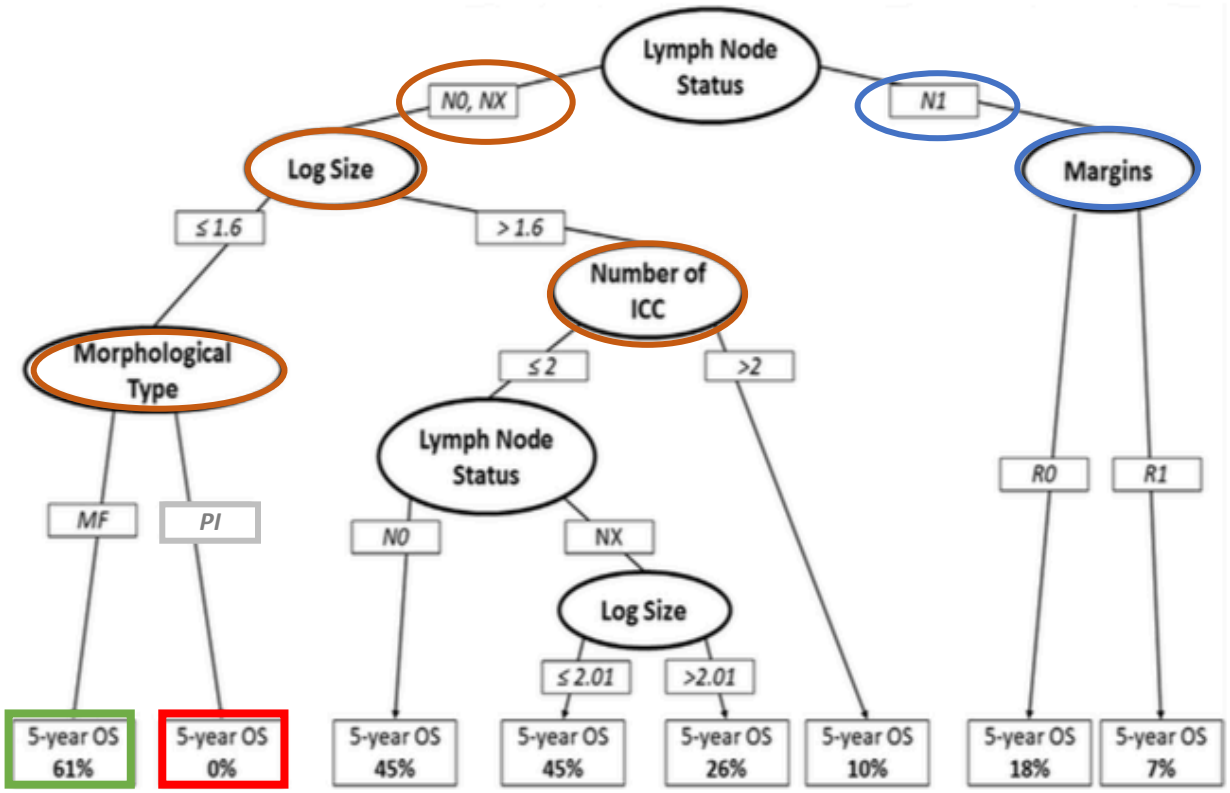

Fig 2. CART model representing the hierarchical association between tumor burden (log tumor size and number of tumors) and the other clinicopathological variables to predict patients' survival.

MF: mass forming
PI:Periductal infiltrating

Conclusions

Conventional HCC

- The tumour load in HCC is an important prognostic factor of OS.

  Tumor size, multiple tumors, bilobar tumors and vascular invasion are prognostic factors of bad survival

- However, these factors do not constitute a formal contra-indication for surgical resection that remains the best treatment option when R0 resection, leaving enough liver volume is possible in patients without extrahepatic disease.

- These prognostic factors have however to be considered when they are multiple in order:

- to make an appropriate selection of patients
- to make informed decisions about surgical resection versus other non-surgical options based on the expected OS in high risk patients.

The use of the risk score can help to better select the patients

Fibrolamellar Carcinoma

- More advanced stage (lymphnode metastases), which did not affect prognosis.
- Despite high recurrence rates, durable overall survival are achieved with surgical resection of recurrent disease

Conclusions

Intrahepatic cholangiocarcinoma (ICC)

- ✓ Prognostic factors of OS of ICC are

- lymphnode metastases
- tumor size
- number of tumors
- tumor type morphology
- vascular invasions
- age

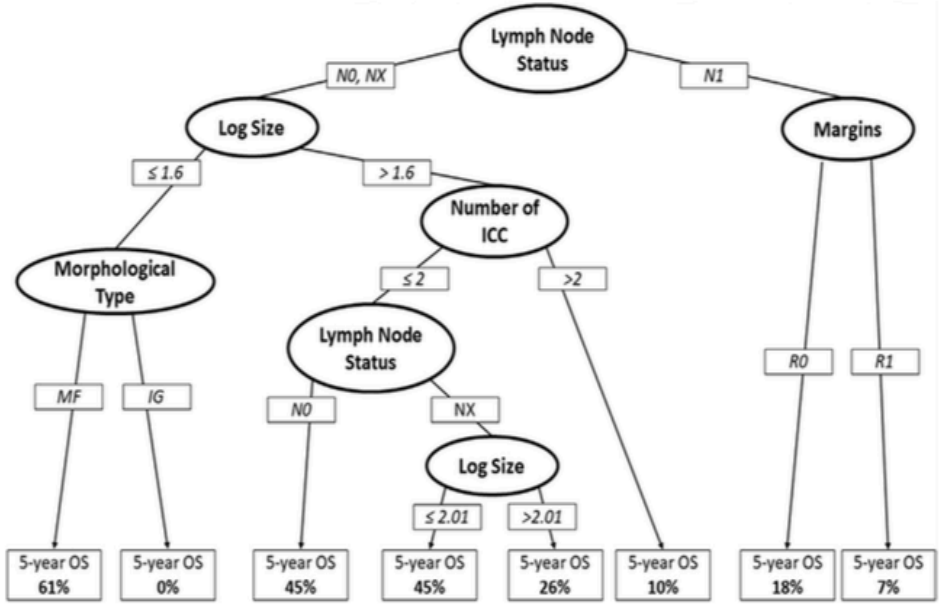

Fig 2. CART model representing the hierarchical association between tumor burden (log tumor size and number of tumors) and the other clinicopathological variables to predict patients' survival.

- ✓ Radical liver resection remains the best treatment (if no extrahepatic disease)
- ✓ A better selection of patients for surgery should be based by using the normogram or the CART model
- ✓ Patients who presents invaded lynphnodes and who are at high risk to have a R1 surgery have poor prognosis (7% 5-Years OS)
- ✓ Patient who have periductal infiltrating morphological type have the worst prognosis even if the tumor is small and if lymphnode status is N0

Thank you for your attention
